

Introduction to R

November 5, 2025

Alliance Bioversity International & CIAT

What is R?

- It is an object-oriented programming language, focused on computation or statistical processing.
- It is free and open source.
- It integrates a wide variety of graphical and statistical techniques.
- It is a very understandable programming language.

Why to use R

- It is a tool that allows us to automate many processes
- It is easy to understand and use
- It has a large community of developers worldwide
- It is equipped with the most up-to-date statistical analysis techniques
- And many more ...

RStudio Desktop

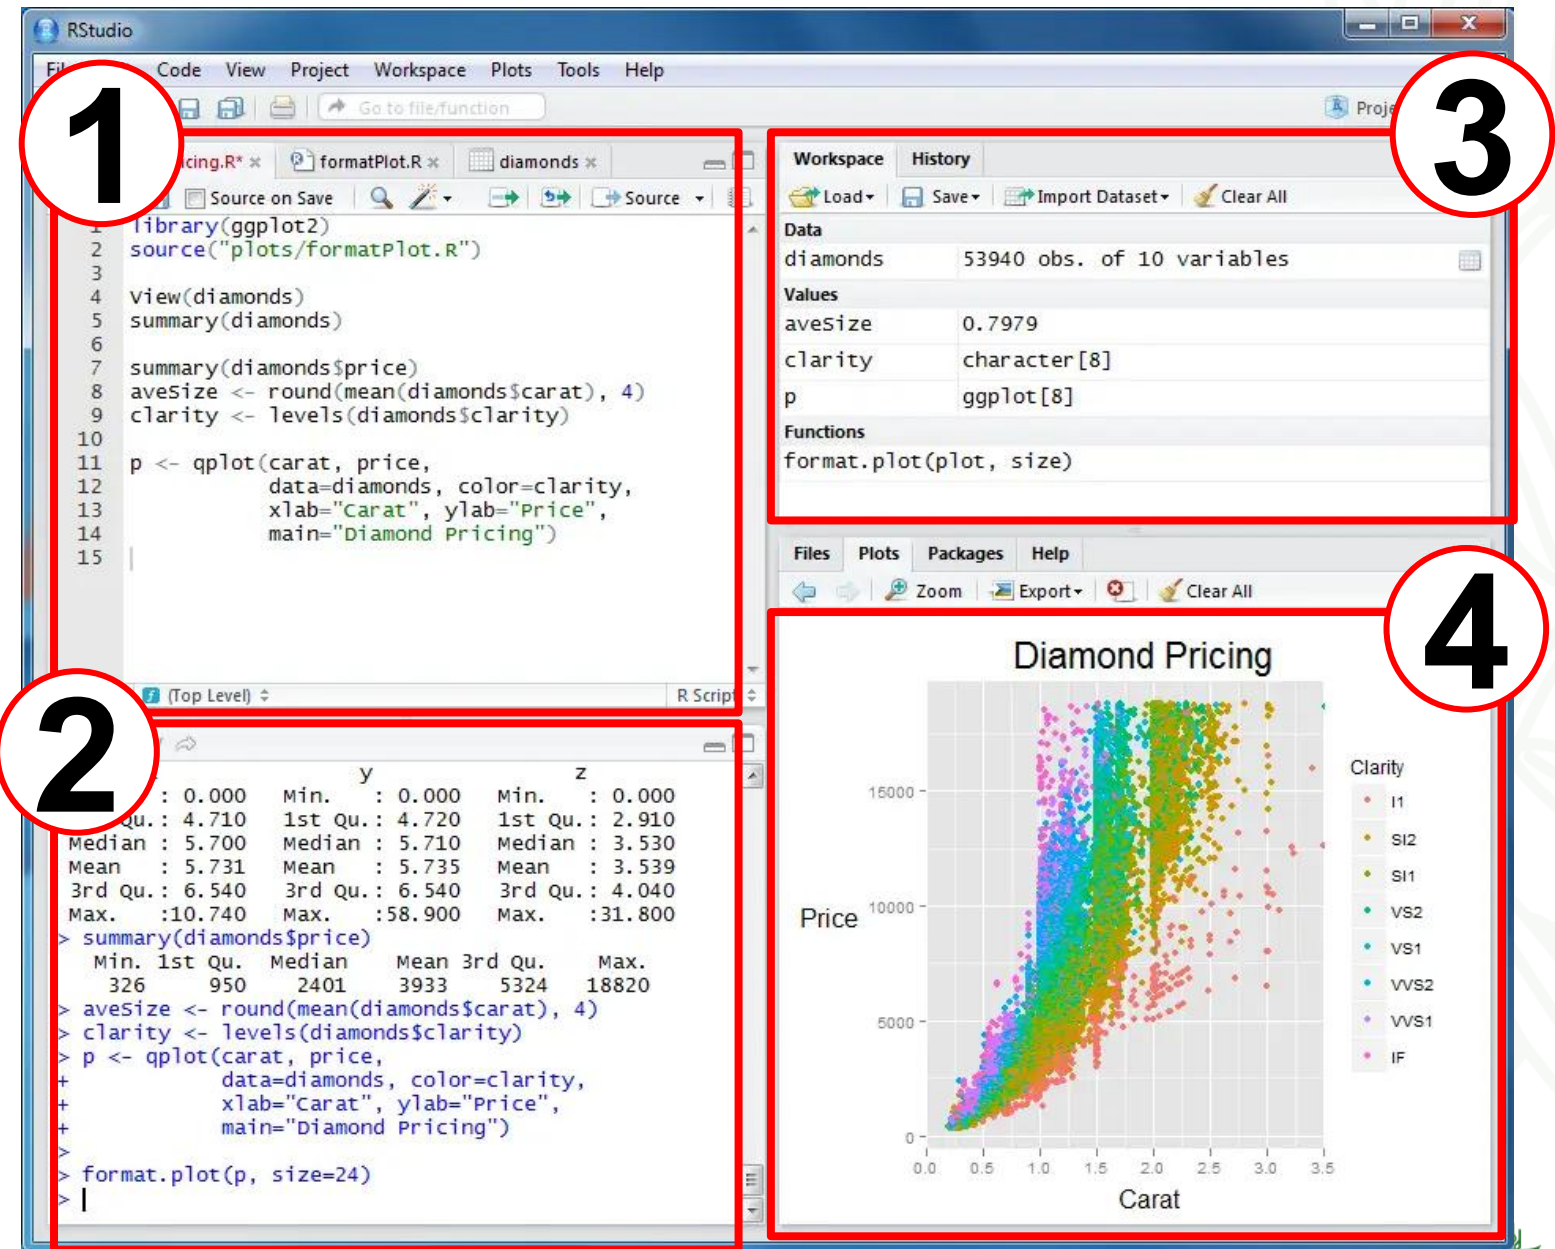

- It is an IDE or integrated development environment.
- It is a program that integrates several functionalities oriented to facilitate the programming of routines.
- It has a more developed graphical GUI interface. In most cases they are multiplatform.
- By integrating all the tools in one place it makes our life easier.
- We can download it from this link:

<https://posit.co/downloads/>

RStudio (GUI)

1. Script editor
2. Console/Terminal
3. Workspace
4. Graph viewer, library and help page

García Márquez

One Hundred Years of Solitude

Harper & Row

MANY YEARS LATER, as he faced the firing squad, Colonel Aureliano Buendía was to remember that distant afternoon when his father took him to discover ice. At that time Macondo was a village of twenty adobe houses, built on the bank of a river of clear water that ran along a bed of polished stones, which were white and enormous, like prehistoric eggs. The world was so recent that many things lacked names, and in order to indicate them it was necessary to point. Every year during the month of March a family of ragged gypsies would set up their tents near the village, and with a great uproar of pipes and kettledrums they would display new inventions. First they brought the magnet. A heavy gypsy with an untamed beard and sparrow hands, who introduced himself as Melquíades, put on a bold public

A large, disorganized pile of numerous small, rectangular white cards scattered across a solid black background. Each card contains a short segment of text in a black, sans-serif font. The text fragments are cut off at the edges, creating a collage-like effect. Some legible words and phrases include "picture", "behind", "those", "spring", "time", "size", "whisper", "through", "stare", "see", "your", "moment", "leave", "purple", "delirious", "pinow", "worship", "may", "for", "in", "like", "an", "po", "eat", "prod", "fri", "m", "n", "t", "e", "s", "l", "q", "tell", "sing", "hine", "pole", "it", "blue", "rob", "W.", "Visit", "the", "and", "pu", "ke", "clim", "lat", "s", "eat", "n", "t", "f", "r", "i", "d", "p", "o", "n", "g", "y", "w", "h", "e", "r", "e", "a", "c", "k", "o", "f", "t", "h", "e", "p", "a", "s", "t", "e", "r", "n", "e", "r", "e", "a", "r", "t", "h", "e", "c", "e", "n", "t", "u", "r", "y", "t", "h", "e", "p", "a", "s", "t", "e", "r", "n", "e", "r", "e", "a", "r", "t", "h", "e", "c", "e", "n", "t", "u", "r", "y". The cards are oriented in various directions, some overlapping others, creating a sense of chaotic movement or a collection of random thoughts.

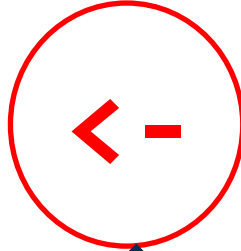

A circular arrangement of 26 letters of the alphabet, starting with 'W' at the top and proceeding clockwise: W, X, Y, Z, A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, U, V.

Basic concepts

What is an object/variable?

- In object-oriented programming, an object is an empty container that the programmer can fill with whatever they decide.
- These containers are often referred to as "variables" in R due to the common use of the term in statistics.
- Variables are composed of values that have different types, such as text, numeric, logical, integer, and others.
- Variable names cannot contain spaces, special characters, or numbers at the beginning.

var_name  **value**

Assignment symbol

Types of values in R

- Logical: TRUE, FALSE
- Integers: 1, 2, 3, 4, ...
- Real Numbers: 1.342, 3.45565, 0.0879985
- Character/Text: “string,” “text”
- Missing Values: NA
- Non-calculable values: NaN
- Very large/small values: Inf, -Inf
- Null values: NULL

How can you identify the type of values in a variable?

R provides tools for determining the types of values:

is(variable) and **class(variable)**. These commands display the value type on the screen.

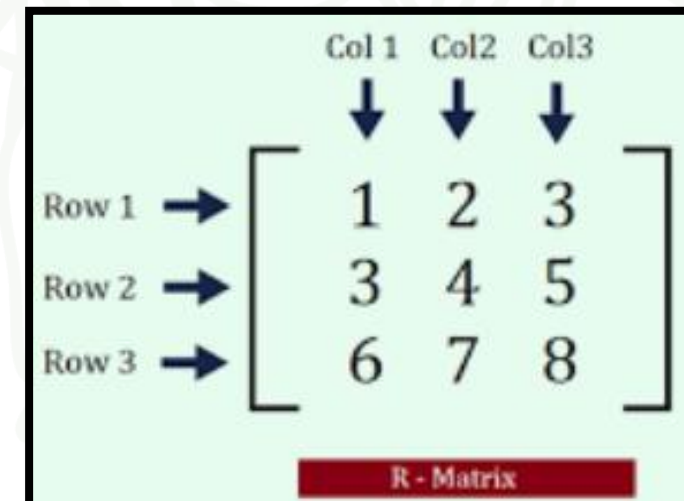

Vectors and matrices – Basic data structures

- **Vectors:**

- In programming, objects often consist of multiple ordered and indexed values.
- These are referred to as “vectors” in R and are fundamental to the programming process.
- Often, variables are composed of vectors.

- **Matrices:**

- A collection of elements (numbers) arranged in rows and columns.
- Every row and column is considered a vector.
- Matrices must have a fixed number of rows and columns.

Indexing

- All objects/variables in R have a way to access their elements.
- **Vectors:** Elements are ordered sequentially, starting from position 1.
 - Access syntax: Variable[position].
- **Matrices:** Access elements by specifying the row and column indices.
 - Matrix[row number, column number] – extracts a single cell value.
 - Matrix[row number,] – extracts the entire row.
 - Matrix[, column number] – extracts the entire column.

Exercise

1. Create a vector containing the **first ten letters** of the alphabet.
2. Assign it to the variable “vec_exercise”.
3. Obtain the letters in **positions 3, 7, and 9**, then print them in the console.
4. Obtain the **first five letters**.
5. Obtain the **last five letters**.
6. Reverse the order of the “vec_exercise”.

Data frames

- They are like matrices.
- They are organized into rows and columns.
- You can name both rows and columns.
- They allow all types of values and do not affect each other.
- This is the most used format.
- All of its elements are easily accessible.

Array

Algorithmic thinking

- A set of systematic operations performed to solve a type of problem.
- Algorithmic thinking involves abstraction, modeling the problem, logical deduction, synthesizing a solution, and writing the correct algorithm.

Exercise

Scenario:

The first monthly sales totals for four stores in the listed cities for 2024 are provided. Calculate each store's total sales for the quarter.

1. Identify the inputs.
2. Define the desired outcome.
3. Establish steps to process inputs and convert them into the desired outcomes.

	Month		
Sales points	January	February	March
Cali	3643	4652	2145
Bogotá	2011	4345	4708
Medellín	2820	1995	3273
Cartagena	4487	3574	4832

Solution

	Month			
Sales points	January	February	March	Total
Cali	3643	4652	2145	10440
Bogotá	2011	4345	4708	11064
Medellín	2820	1995	3273	8088
Cartagena	4487	3574	4832	12893

- **Inputs:**

- Table showing monthly sales totals.
- The rows contain records of sales points in cities.
- The columns contain monthly sales data.

- **Processing:**

- Sum the rows and enter the total in the last column.

- **Outputs:**

- Table showing the sum of monthly sales (quarter total) for each sales point.

What if I am interested in total sales per year?

Functions

$$\sigma^2 = \frac{\sum_1^N (x_i - \bar{X})^2}{N}$$

$$g(x) = \frac{x+3}{2x+1}$$

$$Mean = \bar{\chi} = \frac{\sum_i^n \chi_i}{n}$$

What is a function?

- A function is a type of object.
- It is the foundation of all programming in R.
- A function is defined as a set of processes or algorithms that perform a specific task or calculation.
- Functions require INPUT values, PROCESS them, and must return an OUTPUT.

How are functions defined in R?

Functions have a specific structure:

1. A name must be assigned to the function.
2. Input values must be specified. These values can be of any type or structure that we have seen before, such as data frames, vectors, or matrices.
3. The function should perform an operation based on the input values.
4. Finally, it must return at least one object, which can be of any type.

Function	Description
mean()	Calculates the arithmetic mean of a numeric vector.
sum()	It returns the sum of all the elements in a vector or array.
length()	It returns the number of elements in a vector or list.
head()	Displays the first few rows of a data frame or the initial elements of a vector.
tail()	Displays the last few rows of a data frame or the final elements of a vector.
seq()	Generates a sequence of numbers based on a specified start number, end number, and step size.
sort()	It sorts a vector in ascending or descending order.
paste()	Concatenates strings using a specified separator.
which()	It identifies the indices of the elements in a vector that meet a given condition.
table()	It creates a frequency table of the elements in a vector or factor.

R libraries

What is a library?

- In R, packages or libraries are sets of functions designed to solve a variety of problems, primarily statistical ones.
- R comes with a series of installed packages called "base", which contain basic statistical processing functions.
- R provides the ability to install new packages when our operations or processes require more specialized functions that are not included in the "base" package.
- Each package includes helpful documentation explaining the contents, functions, and other details.
- R offers a massive catalog of packages thanks to the large community dedicated to developing new ones.
- Essentially, there is a package designed for almost any task we can think of or need to perform. You just need to know how to find it.

How are packages installed in R?

install.packages("package_name")

- This command downloads the package from the CRAN repository.
- This command should only be called once.
- The package will be installed, but it has not been called yet.

Unquoted

library(package_name)

- This function loads the package functions into the R session.
- It's good practice to load the libraries at the beginning of the script only.

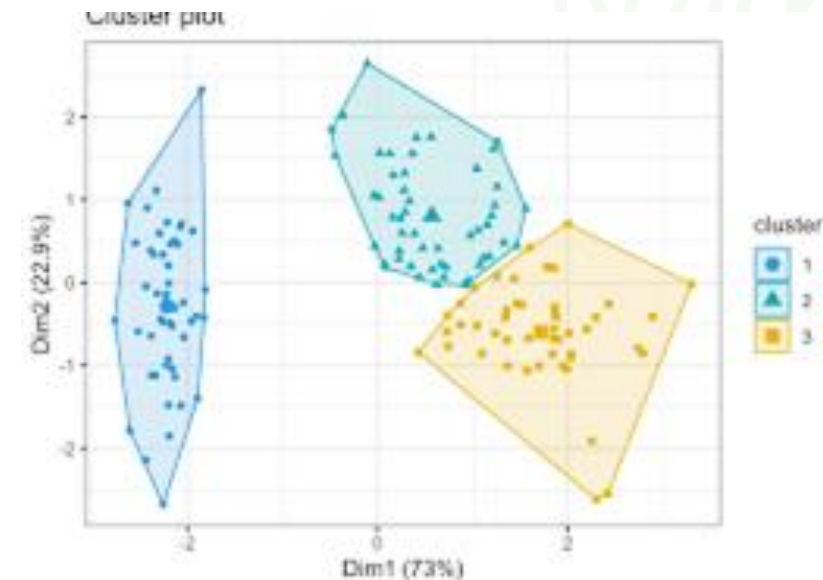

or simply:

```
library(pacman); pacman::p_load(package_name)
```
